

## **FEEDING DEVICE FOR A TABLE SAW**

## BACKGROUND OF THE INVENTION

## 1. Field of the Invention

The present invention relates to a feeding device, and more particularly to feeding device for a table saw. The feeding device of the present invention can be used to a long distance cutting.

## 2. Description of Related Art

8 A conventional feeding device for a table saw comprises a moving seat  
9 slidably mounted on one side of a worktable of the table saw. A graduation plate  
10 is partially rotatably mounted to the moving seat and a pushing rod laterally  
11 extends from the graduation plate for abutting against a datum of a workpiece.  
12 A threaded rod upwards extends from the moving seat and penetrates through  
13 the graduation plate. A nut is screwed onto the threaded rod to hold the  
14 graduation plate in place after adjusting an operating angle.

15           However, the adjusting range of the graduation plate on the  
16 conventional feeding device for a table saw is smaller than 180 degrees.  
17 Consequently, the conventional feeding device for a table saw is useless when  
18 the workpiece is greater than the distance between the pushing rod and the saw  
19 blade. Furthermore, the quality of cutting cannot be effectively controlled when  
20 the nut is loosened from the threaded rod due to a vibration of the table saw  
21 during operating. Consequently, the conventional feeding device for a table saw  
22 in accordance with the prior art needs to be advantageously altered.

23 The present invention has arisen to mitigate and/or obviate the  
24 disadvantages of the conventional feeding device for a table saw.

1        **SUMMARY OF THE INVENTION**

2              The main objective of the present invention is to provide an improved  
3              feeding device for a table saw. The feeding device of the present invention can  
4              be used to a long distance cutting.

5              To achieve the objective, the feeding device for a table saw in  
6              accordance with the present invention comprises a sliding board slidably  
7              mounted on one side of a worktable of the table saw and having a moving  
8              direction corresponding to a saw blade. The sliding board includes two grooves  
9              defined in two opposite sides thereof and respectively parallel to the moving  
10             direction of the sliding board. A moving seat is selectively slidably mounted on  
11             one side of the sliding board. A pushing rod is laterally slidably mounted to the  
12             moving seat and has a first side forming a pushing face for abutting against a  
13             datum of a workpiece. A first locking device and a second locking device  
14             respectively extend through the pushing rod and the moving seat to selectively  
15             hold the pushing rod and the moving seat in place for confirming a cutting angle  
16             of the workpiece.

17             Further benefits and advantages of the present invention will become  
18             apparent after a careful reading of the detailed description with appropriate  
19             reference to the accompanying drawings.

13 **DETAILED DESCRIPTION OF THE INVENTION**

14 Referring to the drawings and initially to Figs. 1-3, a feeding device for  
15 a table saw in accordance with the present invention comprises sliding board  
16 (10) adapted to be slidably mounted on one side of a worktable of the table saw  
17 and having a moving direction adapted to correspond to a saw blade of the table  
18 saw. A moving seat (20) is selectively slidably mounted on one side of the  
19 sliding board (10). A pushing rod (30) is laterally slidably mounted to the  
20 moving seat (20). A first locking device (40) and a second locking device (50)  
21 respectively extend through the pushing rod (30) and the moving seat (20) for  
22 confirming a cutting angle of a workpiece. A graduation plate (60) is securely  
23 mounted to a bottom of the moving seat (20).

24 The sliding board (10) includes two grooves (11) defined in two

1 opposite sides thereof. The two grooves (11) are respective parallel to the  
2 moving direction of the sliding board (10).

3 The moving seat (20) includes a rail (21) laterally extending therefrom  
4 and having a T-shaped cross-section. A bore (22) is defined in and extending  
5 through the moving seat (20). A steel ball (23) is movably received in the bore  
6 (22) and partially extending through a bottom of the moving seat (20). A spring  
7 (24) is longitudinally compressively received in the bore (22) and a bolt (25) is  
8 partially screwed into the bore (22) to hold the spring (24) and the steel ball (23)  
9 in place. An indicator (26) is detachably mounted to a first end of the moving  
10 seat (20) for indicating the rotating angle when the moving seat (20) is rotatably  
11 moved relative to the graduation plate (60).

12 The pushing rod (30) includes a first side and a second side opposite to  
13 the first side of the pushing rod (30). The first side of the pushing rod (30) forms  
14 a pushing face (31) adapted to abut against the workpiece and the second side of  
15 the pushing rod (30) has a sliding groove (32) laterally defined in the pushing  
16 rod (30). The sliding groove (32) includes a cross-section having a shape  
17 corresponding to that of the rail (21). The rail (21) of the moving seat (20) is  
18 slidably received in the sliding groove (32) in the pushing rod (30) such that the  
19 pushing rod (30) can be moved relative to the moving seat (20) when the first  
20 locking device (40) is detached from the pushing rod (30) and the second  
21 locking device (50) is loosened.

22 A distance between the first locking device (40) and the saw blade of the  
23 table saw is shorter than that between the second locking device (50) and the  
24 saw blade of the table saw. The first locking device (40) includes a threaded rod

1 (41) rotatably extending through the pushing rod (30). The threaded rod (41)  
2 has a handle (411) extending therefrom for easily operating the threaded rod  
3 (41). The handle (411) has a diameter greater than that of the threaded rod (41)  
4 and abuts on a top surface of the pushing rod (30). A sliding block (42) is  
5 slidably received in a corresponding one of the two grooves (11) in the sliding  
6 board (10) and has a threaded hole (421) defined in the sliding block (42). The  
7 threaded hole (421) extending through the sliding block (42) and the threaded  
8 rod (41) screwed into the threaded hole (421) to hold the sliding block (42) in  
9 place. The second locking device (50) is the same as the first locking device  
10 (40). The second locking device (50) has a threaded rod (51) extending through  
11 the moving seat (20) and having a handle (511) extending from the threaded rod  
12 (51). A sliding block (52) is slidably received in a corresponding one of the two  
13 grooves (11) in the sliding board (10). The sliding block (52) of the second  
14 locking device (50) has a threaded hole (521) defined therein and extending  
15 through the sliding block (52). The threaded rod (51) of the second locking  
16 device (50) is screwed into threaded hole (521) in the sliding block (52) of the  
17 second locking device (50) to hold the sliding block (52) of the second locking  
18 device (50) in place.

19       The graduation plate (60) is attached to the sliding block (52) of the  
20 second locking device (50). The graduation plate (60) has a multiple dimples  
21 (61) defined therein for partially receiving the steel ball (23). Each dimple (61)  
22 is situated on a certain angle for quickly orientating the moving seat (20) and  
23 the pushing rod (30) in the certain angle. The graduation plate (60) has a series  
24 of scales (62) formed on an arc edge thereof and corresponding to the indicator

1 (26) of the moving seat (20) for indicating the operating angle of the moving  
2 seat (20) and the pushing rod (30).

3 With reference to Fig. 4 and 5, the moving seat (20) and the pushing rod  
4 (30) can freely adjusting the operating angle when the first locking device (40)  
5 and the second locking device (50) are loosened. The user can clearly read the  
6 operating angle via the indicator (26) and the series of scales (62) on the  
7 graduation plate (60) when the moving seat (20) and the pushing rod (30) is  
8 adjusted.

9 With reference to Figs. 6 and 7, the pushing face (31) forwards abuts  
10 against a datum of the workpiece for a short distance cutting. With reference to  
11 Figs. 8 and 9, the indicator (26) is detached from the moving seat (20) and  
12 attached to a second end of the moving seat (20). The threaded rod (41) is  
13 detached from the sliding block (42) and the pushing rod (30) and the threaded  
14 rod (51) of the second locking device (50) is loosened. The threaded rod (41) of  
15 the first locking device (40) is screwed into threaded hole (421) in the sliding  
16 block (42) of the first locking device again to hold the sliding block (42) of the  
17 first locking device (40) in place after the moving seat (20) turning about 180  
18 degrees and the threaded rod (51) of the second locking device (50) being  
19 tightened again. Then, the pushing face (31) of the pushing rod (30) backward  
20 abuts a datum of workpiece that needs a long distance cutting. For the long  
21 distance cutting, the user forwards pushes the workpiece with the feeding  
22 device of the present invention to finish the long distance cutting of the  
23 workpiece.

24 As described above, the feeding device for a table saw in accordance

1 with the present invention has the following advantages.

2       1. The work range of the feeding device of the present invention is  
3 greater than that of the conventional feeding device for a table saw. The feeding  
4 device can be provided for a great workpiece that needs a long distance cutting  
5 after turning the moving seat (20) about 180 degrees.

6       2. The first locking device (40) and the second locking device (50)  
7 provide a stable support to the pushing rod (30) during cutting.

8       3. The first locking device (40) and the second locking device (50)  
9 hardly automatically loosen at the same time such that the relation between the  
10 pushing rod (30) and the moving seat (20) is stable.

11       4. The operating angle of the feeding device is easily adjusted because  
12 the user only needs to loosen the first locking device (40) and the second  
13 locking device (50) before adjusting the operating angle of the feeding device in  
14 accordance with the present invention.

15       Although the invention has been explained in relation to its preferred  
16 embodiment, it is to be understood that many other possible modifications and  
17 variations can be made without departing from the spirit and scope of the  
18 invention as hereinafter claimed.
